in statistics a power law is a functional relationship between two quantities where a relative change in one quantity results in a relative change in the other quantity proportional to a power of the change independent of the initial size of those quantities one quantity varies as a power of another the power law also called the scaling law states that a relative change in one quantity results in a proportional relative change in another the simplest example of the law in action is a square if you double the length of a side say from 2 to 4 inches then the area will quadruple from 4 to 16 inches squared power laws arise in many fields of knowledge from word usage in linguistics to income distributions in economics there is an enormous literature observing and calculating power laws in stakeholders a power law also called a scaling law is a relation of the type $y = ax^\beta$ where y and x are variables of interest β is called the power law exponent and a is typically an unremarkable constant for instance if x is multiplied by a factor of 10 then y is multiplied by 10^β one says that y scales as x to the power β some empirical power laws power law pl is one of the
