publius syrus stated back in 42 b c you cannot put the same shoe on every foot maxim 596 though written long before the advent of forensic science syrus maxim summarizes the theme of forensic medicine of the lower extremity human identification and trauma analysis of the thigh leg and foot put simply the lower extremity is a tremendously variable anatomic region this variation is beneficial to forensic experts differences in the leg and foot can be used to establish individual identity analysis of damage to the lower limb can be used to reconstruct antemortem perimortem and postmortem trauma as a forensic anthropologist i analyze cases involving decomposed burned m mified mutilated and skeletal remains many of the corpses i examine are incomplete occasionally i receive nothing but the legs and feet a lower torso dragged from a river a foot recovered in a city park dismembered drug dealers in plastic bags victims of bombings and airline disasters and the dead commingled in common graves though the leg and foot contain much that is useful in forensic analysis before this publication investigators faced a twofold problem little research that focused on the lower extremity was available in the literature and the existing research was published in diverse sources making its location and synthesis a daunting task

when computed tomography ct was developed and introduced by hounsfield 1973 a new era of clinical diagnostic potential began at the same time ct created new difficulties in that the physicians who had to deal with the ct images were not

acquainted with their interpretation therefore it became necessary to compare ct scans with anatomical sections which gave additional information by virtue of their higher resolution the different colors and consistencies of the structures and the possibility to trace these structures across several sections several atlases comparing ct scans and anatomical sections were published soon after the introduction of the new technique the resolving power of the new scanners has increased considerably necessitating a renewed comparison between ct scans and anatomical sections a threefold need for higher quality anatomical sections has also become evident first tissue preservation should be excellent second the sections should not be thicker than the scans obtained by the ct procedure third the series of sections should be complete in order to permit three dimensional reconstructions we have tried to meet these requirements restricting ourselves to the analysis of the lower extremity the leg had to be scanned serially then cut in serial sections in such a way that the ct planes and the anatomical sections corresponded optimally as many sections had to be illustrated as were necessary to demonstrate changes in the internal structure of the extremity wherever they occurred
